AC Power in a Purely Resistive Circuit. We have seen thus far, that in a dc circuit, power is equal to the product of voltage and current and this relationship is also true for a purely resistive AC circuit. Resistors are electrical devices that consume energy and the power in a resistor is given by $p = VI = I^2 R = V^2 / R$. This power is always positive.

~~University Physics Volume 2~~

In DC circuit the power dissipated in a resistive circuit is given by:
where: $P =$ power (W) $U =$ potential difference (PD) (V) $I =$ current (A) $R =$ resistance (Ω)
In AC circuits the instantaneous values of voltage, current and therefore power are constantly changing. However, at any instant we can still say that: where: $p =$ instantaneous power (W)

Some important cases for the power to load are: Short Circuit: if there is no resistance between the terminals, $R = 0$, the power to load is $P_L = V^2 \times 0 / (R_s + 0)^2 = 0$. $R_s = 0$. No power can be extracted from a short circuit: there must be a resistance to extract power. Open Circuit: if the terminals are disconnected then there is an

AC Power in a Purely Resistive Circuit. The resistor is an electrical component which consumed the electrical power of the ac circuit. In a purely resistive circuit, the current flows through the resistor is in phase with the supply voltage, i.e., the waves form of the voltage and current is in phase with each other. The zero-degree phase difference occurs between the waveform of voltage and current. AC power in a Purely Inductive Circuit
