Rheology is a branch of physics, and it is the science that deals with the deformation and flow of materials, both solids and liquids.

Understanding the influence of magnetic fields on the rheological behavior of flowing cement paste is of great importance to achieve active rheology control during concrete pumping. In this study, the rheological properties of cementitious paste with water-to-cement (w/c) ratio of 0.4 and nano-Fe₃O₄ content of 3% are first measured under magnetic field.

Rheological studies are important for the design of unit operations, high quality assurance of foods and beverages and process optimization. In addition, rheological approaches are employed mainly as essential tools for food engineering, since rheology is linked to food processing and stability, as well as to sensory perceptions.

The pipeline transport characteristics of ICPB need to be investigated to promote its application, which are influenced by the rheological properties. The objective of this study is to investigate the rheological properties of ICPB by means of experimental and computational fluid dynamics (CFD) methods. The rheological parameters were measured using a rheometer and the slump test was performed in a cylinder slump.

However, these researchers are aimed to study on function properties of rice starch, and its functional properties incompletely replace the physicochemical properties of the whole rice grain. Ahmed et al studied the thermal and dynamic properties of rice starch and discovered significant differences between rice starch and rice flour . In general, due to the differences among varieties, regions and environments, the content of basic components in rice grain varies significantly.

Abstract. We examined changes in rheological properties of nonequibrated spin-coated thin films of isotactic polystyrene (iPS) and isotactic poly (para- methylstyrene) and blends thereof by dewetting experiments. For 200 nm thick films and a systematic variation of dewetting temperature, we focused on changes in the amount of residual stresses and the corresponding relaxation times as a function of iPS content.

After the HPCD process, the foaming properties and emulsifying properties of LWE may change. Precisely because of its excellent technical features, LWE is widely applied in the food industry as an important food ingredient. However, there is still no study about the influence of HPCD treatment on the processing quality characteristics of LWE.

Knowledge of the rheological properties of non-Newtonian fluids is critical for modeling in polymer-processing equipment such as injection molders, extruders, and blow molders. Rheological measurements can be obtained through standard flows, such as shear flow and elongational flow. In our research, we modeled the rheological properties of polymeric fluids in several types of experiments: transient and steady shear flow, small amplitude oscillatory shear flow, transient elongational flow, and step-strain shear flow. The accuracy of modeling calculations depends critically on the performance of the rheological model used. Differential constitutive models with a single relaxation time can be used for exploratory fluid dynamics research and provide insight into the qualitative effects of viscoelasticity in complex flow fields. However, differential models with a single relaxation time give a poor quantitative description of rheological properties, since most non-Newtonian media exhibit not just one, but a whole spectrum of relaxation times; therefore multiple relaxation modes models were used in our research. One of the coupled linear relaxation models, the Two Coupled Maxwell Modes (TCMM)

Model, was used to describe quantitatively shear-thickening behavior, which can be observed under certain conditions for high molecular weight polymers dissolved in low viscosity solvents. In this case, the shear viscosity of the polymer solution increases with increasing shear rate. A full parameterization of the TCMM Model to the experimental data from the literature provided a thorough understanding of the significance of the model parameters and a clear insight into the peculiar behavior of shear thickening in dilute polymer solutions. The primary part of the research focused on models with linear springs. A typical, industrial-grade, low-density polyethylene polymer was studied using three types of multi-mode models: i) uncoupled linear relaxation models; ii) coupled linear relaxation models; iii) uncoupled non-linear relaxation models. The data from small amplitude oscillatory shear flow and steady shear flow were fitted to obtain the parameters of the different models using the Nelder and Mead Downhill Simplex method. Then the predictions for the other standard flows mentioned in the first paragraph were compared with experimental data. This allowed us to determine the degree of the performance of the different models with regards to the corresponding system studied. Overall evaluations of model performance were presented in detail. Finally, we tested the effects of spring type on the performance of the models described above. We replaced the linear elastic springs in all of the prior models with nonlinear springs to determine whether this would improve model performance in elongational flow. The Finitely-Extensible Nonlinear Elastic Spring Model was used to describe the nonlinear elastic springs. The result was negative, however: no improvement was obtained over the linear spring models and more parameters were present which required further fitting to experimental data.

A special triaxial apparatus allowing for a gammadetric measurement of local density is used to study the influence of experimental conditions in triaxial tests. Compression tests performed along different stress paths and classical extension tests provide reliable results on the rheological behavior of sand up to large strains and permit characterization of the limit state of perfect plasticity.
